Cynbit LeadIQ

AI Opportunity Report

AI-assisted lead qualification and response drafting

Prepared for: Cynbit Technologies | Prepared as an assessment prototype | 16 October 2026

Executive summary

LeadIQ is a small proof of concept that turns a prospective customer's free-text inquiry into a structured lead profile, a rule-based priority score, qualification gaps, and a suggested response for human review. It is designed around a practical workflow opportunity: reduce repetitive first-pass triage while keeping sales decisions and outbound communication under human control.

This is an opportunity hypothesis and prototype, not evidence of production impact. No customer outcomes, conversion improvements, or time savings have been measured in this assessment.

1. Business context and opportunity

Cynbit Technologies publicly describes work across AI automation, autonomous agents, LLM automation, AI voice agents, software development, CRM automation, and technical SEO. Its service page specifically mentions assistants that manage leads and coordination, and LLM automation for manual data entry and document handling. These published capabilities make lead qualification a relevant workflow to explore. [1][2]

A lead may arrive as a short form message, email, or chat inquiry. Before a team member can respond, they may need to identify the service requested, clarify the business goal, determine whether budget and timing are known, identify integrations, and prepare a first response. LeadIQ proposes to assist with that initial preparation.

Problem statement

- Unstructured inquiries may require repetitive manual reading and re-entry into internal tools.
- Important qualification fields may be omitted, leading to additional follow-up exchanges.
- Prioritization can vary between reviewers if criteria are informal or undocumented.
- A first response may take longer when staff must compose each message from scratch.

These are plausible workflow risks to validate with Cynbit staff; they are not claims that the company currently experiences them.

2. Proposed solution

LeadIQ uses a compact pipeline to produce a consistent review screen from a single inquiry. In live mode, a configured Gemini model attempts structured extraction. If the service is unavailable, a local heuristic fallback can provide a clearly labelled demonstration result. Python rules calculate priority from available qualification signals. The result is editable and downloadable, but the prototype does not send email or modify a CRM.

Core user journey

- Paste or select a sample customer inquiry.
- Extract service category, business goal, stated budget, timeline, integrations, and missing information.
- Calculate a transparent priority score and show the reasons produced by the rule engine.
- Review and edit the suggested response, then download the draft.
- A human decides whether the information is accurate and whether to contact the lead.

3. Illustrative use cases

- **AI automation inquiry:** identify the intended workflow, business outcome, budget, timing, and required systems.
- **CRM integration inquiry:** surface the named CRM or integration and ask for the current workflow and success criteria.
- **Document-processing inquiry:** identify document types, extraction fields, expected volume, and downstream system.
- **Incomplete inquiry:** highlight missing budget, timeline, integration, or business outcome instead of assuming details.

4. Expected value and measurement plan

Potential benefits should be treated as hypotheses and measured in a pilot rather than promised in advance.

Hypothesis	Measure	Method
Less first-pass triage effort	Median review time per inquiry	Compare a baseline sample with assisted review
More consistent qualification	Field completeness and reviewer agreement	Score a labelled set of representative inquiries
Faster preparation of first replies	Time to approved draft	Record timestamps during a small supervised pilot

Hypothesis	Measure	Method
Fewer unsupported statements	Grounding error rate	Human-review rubric on sampled drafts

5. Risks and controls

- **Incorrect extraction:** reviewers verify all extracted fields before relying on them.
- **Overconfident scoring:** a 0–10 score is a configurable heuristic, not a calibrated conversion probability. Display reasons and missing fields alongside it.
- **Hallucinated promises:** restrict reply drafting to approved service descriptions and prohibit invented prices, delivery commitments, guarantees, and client references.
- **Prompt injection:** treat customer text as untrusted data and never let it override system instructions.
- **Privacy:** use synthetic inquiries for the assessment; production use requires data-minimization, retention, access-control, and vendor-review decisions.
- **Service outages and quotas:** label fallback output and record the failure; do not represent heuristic output as live AI.
- **Automation risk:** keep sending, CRM writes, and external actions disabled until explicit approvals, audit logs, and rollback controls exist.

6. Recommended next steps

- Validate the workflow with sales or delivery staff and agree on the minimum qualification fields.
- Create a small, consented or synthetic evaluation set with human-labelled categories and fields.
- Tune priority rules with reviewers and document the reason for every score.
- Pilot in shadow mode: generate suggestions without sending messages or changing CRM records.
- Only consider CRM/email integration after accuracy, security, and human-approval requirements are met.

Conclusion

LeadIQ is a credible, narrow prototype aligned with publicly described Cynbit capabilities. Its strongest near-term value is consistent preparation and visibility—not autonomous selling. The next decision should be based on a measured pilot, not assumed ROI.
